Chrome remote desktop host installer windows

Once upon a time, in a world not so far away, access to a computer is remotely required all kinds of costly, complex software and technical know-how. These days, it's a different story. Google's free Chrome Remote Desktop service makes it simpler to access any computer — Windows, Mac, Linux, or Chrome OS — than almost any other desktop or mobile device. You can access all the contents of the remote system and even click around as if it were sitting right in front of it. Chrome Remote Desktop can be useful for signing in to your personal or work computer remotely, and can be just as valuable for peeking into someone else's system — be it your partner's or your mother's — to provide practical help without having to be in the same position. And best of all? Getting the service up and running is easy, as it can be. In fact, all you need to do is decide what kind of connection you want and then complete a few quick steps, and you'll be remotely connected like anyone's business. (Note that Chrome Remote Desktop may not work with google accounts at the corporate level managed by the company. Use Chrome Remote Desktop to access your PC) **1: Prepare your computer for connections** If you want to access your computer from another desktop or mobile device, start by opening Chrome on the host computer (or by downloading and installing Chrome if you're using a Windows, Mac, or Linux system that somehow doesn't already have it). Inside Chrome, go to Google's Chrome Remote Desktop web app and click the circular blue arrow icon inside the box labeled Remote Access Setup. (If you see a blue button marked Activate instead of a blue arrow, congratulations: You're one step ahead! skip the next paragraph and you'll be back in the spotlight.) You'll then be prompted to download chrome's remote desktop extension. Click the blue Add to Chrome button on the page that appears and confirm that you want to continue. Then go back to the original tab and you'll find a message waiting for you to name your computer and move on. **JR Raphael / IDG** You can give your computer any name you want, as long as you recognize it. (Click any image in this story to enlarge it.) After you give the computer a name and click Next, you'll be prompted to create a PIN with at least six digits. For reasons of you'll need this PIN — in addition to signing up to your Google account — to remotely access the computer. (Google says all remote desktop sessions are also encrypted for extra protection.) And that's just about it: your operating system may display a warning that ensures that you want to allow application access to start a remote connection (and some versions of macOS may additionally ask you to grant a pair of permissions to Chrome Remote Desktop in System Preferences), but after you confirm that, the Chrome Remote Desktop tab will show you that the is online and waiting. The PC will remain available every time it turns on and Chrome works (and since Chrome usually starts automatically and runs in the background, it will probably be available every time the computer is awake — period). Just note that if you want connections to remain possible for a long time, you may need to visit your computer's power management settings to make sure the system doesn't go into hibernation (even if the screen closes). If you ever want to turn off remote connections, just go back to remotedesktop.google.com/access or click the Chrome Remote Desktop icon to the right of the browser address bar. You can then click the trash can icon along with your computer name to remove it from the app. Alternatively, you can simply uninstall the app completely by right-clicking its icon and selecting Remove from Chrome. **Step 2: Connect to the computer from another desktop or mobile device** Eco is the easy part: With your host all set for connections, all you have to do to access it from another desktop computer is go to the same Remote Desktop Webpage - remotedesktop.google.com/access - within the Chrome browser. You'll need to sign in to Chrome using the same Google account you used in your welcome system, but you won't need to install specific apps or extensions. you will only see the name of your computer appear, and you can click it to start the connection. After you tap your PIN, you'll be there — and you can scroll through your screen, click and perform whatever you want, and generally use the computer as if you were sitting in front of it. A table at the side of the screen will provide options for setting up the screen and sending complex commands, such as ctrl-alt-del. It will also allow you to synchronize the clipboards between your current computer and the host if you are so inclined that you can copy and paste text seamlessly between the two. **JR Raphael/IDG** The host desktop is fully accessible on a browser tab, with a drop-down table for advanced commands. For mobile access, you'll need to download the Chrome Remote Desktop app for iOS or Android. Provided your phone is connected to the same Google account you used on your computer, the app will automatically display the computer and allow you to sign in to it a quick tap and a keystroke of your PIN. You will then be able to mouse your desktop using your fingers. You can move by sliding in any direction or zooming in with a pinch. In the Android app, scanning down from the top of the screen will reveal a control bar that lets you switch to trackpad mode — in which you can left-click by tapping one finger or right-clicking by tapping two — and switch to a keyboard mode to pull your device's on-screen keyboard and enter text. In iOS, click the menu button in the lower-right corner of the screen to access the same options. **JR Raphael/IDG** Your entire desktop, in the fingers — on your phone. It's not the most stylish way to get around a computer - and you probably wouldn't want to use it for any kind of intensive work - but it can be convenient for quick-hit tasks like restarting your system remotely or grabbing a file you forgot to save to the cloud. Use Chrome Remote Desktop to access someone else's computer **Bespa 1: Prepare your computer for connections** If seeing someone else's screen is what you're looking for, the process for setting up Chrome Remote Desktop is slightly different. And since you probably won't be physically present on the server, you need to provide these instructions to the person who will be there and able to complete this part of the installation. On the computer you want to access remotely, start by going to the Support section of The Google Remote Desktop Web Application. Click the circular blue arrow inside the box labeled Get Support, and then click Add to Chrome in the box that appears, and confirm that you want to install the Chrome Remote Desktop Companion extension. (If you don't see the blue arrow, the extension is already installed — and you're one step ahead. **JR Raphael/IDG** Installation for a remote support session is slightly different, but the end result is the same. Go back to the original tab and you'll find a message instructing you to click create code to give someone else access. When you do this, the site will create a one-time password that will remain valid for only five minutes. Share this code with the person you want to give access to — your phone, email or text message, or whatever works best — and then sit back and wait for it to start connecting. **Step 2: Sign in to the computer from another desktop** The moment you have the password and you're ready to sign in, just go remotedesktop.google.com/support into Chrome on any other computer. Type the password in the Provide support box, and then click Connect to get started. (If you want to sign in from a mobile device, you'll need to open a new Chrome tab on your phone, check the box in the main browser menu to request a desktop version of a site, and then go to the same link from there. your Google account so you can't use it in this environment.) The person at the other end should manually click a button to approve the connection (and macOS users may also have to grant permissions to System Preferences), and then you'll be logged on to their computer and you'll be able to click and control it the same way described in the first part of this guide. Google still has the original version of the Chrome Remote Desktop app published and available in the Chrome Web Store, by the way, but this version has now been officially rejected and is no longer actively supported or maintained. So if you had this in your system. Your. previous use, now is the time to uninstall it and move on to this newer setup instead. It's not even remotely difficult - is it?
